Specifications Are All You Need 💥

Though there is huge hype around AI writing code on its own, the power of vibe coding, and autonomous agents running for weeks to prepare full systems, the reality is far from that. The real key is very accurate specification. 🎯

AI is a super coder. It can generate features, refactor modules, write tests, and even review pull requests. But without clear intent, it will confidently build the wrong thing. And it will do it fast.

Today, domain knowledge matters more than ever. Understanding the architecture. Knowing the tech stack. Anticipating edge cases. Defining constraints. All of this expertise is now required upfront to give precise instructions on what to build.

We are seeing the shift clearly. Studies of AI generated code show higher rates of logic issues, not syntax errors. The code runs. It just does the wrong thing. **Google**'s DORA research has also shown rising bug rates and longer review times as AI adoption increases.

Even **Amazon** responded by launching AWS Cairo, which forces developers to define testable specifications before generating code. That design choice says everything. The bottleneck is no longer writing code. It is defining what the code should do.

In this new world, the roles of programmer, architect, and product manager are collapsing into one. The person who wins is the one who can combine domain insight, system design thinking, and clear specifications.

Code is becoming cheap. Judgment is becoming expensive. 🚀

Here is the uncomfortable question:
If AI can build almost anything you describe, are you skilled enough to describe what truly matters?
