Humans always wanted to fly. Like birds. So, initial attempts were naturally of bio-mimicry, ie bird like wing-flipping machines. Power requirements, maneuverability and payload carrying capacity made these attempts unviable via just the flipping action.

Then came a radical new discovery, an aerofoil section. A static fixed shape, when speeded up, lifts itself plus some more. It dramatically

Drawing parallels with the progress of Artificial Intelligence (AI) now.

Current attempts are of bio-mimicry. Neural networks are inspired from brain neurons. CNNs (Convolutional Neural Networks) mimic visual cortex to an extent.

My intuition says that such approaches may not go far, at least not to the envisioned singularity moment. Some radically new technique is needed to make AI, an AGI (Artificial General Intelligence)..

Waiting for that 'aerofoil moment' ...
